## ABSTRACT

Nanocrystalline LiCoO<sub>2</sub> particles were prepared using ethylene glycol assisted Pechini process and rare earth oxides (Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub>) coated nanocrystalline LiCoO<sub>2</sub> particles were prepared using newly developed polymeric resin process. The prepared particles were characterized using TG/DSC, FTIR, XRD, SEM and XRF. The electrical conductivities were evaluated through impedance measurements for the pure, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated nanocrystalline LiCoO<sub>2</sub> particles.

**Keywords:** Nanocrystalline LiCoO<sub>2</sub> particles, Surface modification, XRD, FTIR, SEM, XRF, Impedance spectroscopy, Electrical Conductivity.

## 1.INTRODUCTION

There is a great demand for energy storage devices, such as rechargeable batteries. Among the family of rechargeable batteries, Li-ion batteries have been an increasing potential applications in portable electronic devices due to their high energy density and high specific capacity [1]. Among the available positive electrode materials, layer structured LiCoO<sub>2</sub> is the most preferred electrode used in commercial Li-ion batteries because of its high theoretical capacity (274 mAhg<sup>-1</sup>) [2-5]. However, LiCoO<sub>2</sub> exhibits a capacity fading at high rates due to its structural instability and reactivity with electrolyte. During charge and discharge process, Li<sub>1-x</sub>CoO<sub>2</sub> undergoes a phase transition from hexagonal to monoclinic, if x value exceeds 0.5 and hence, leads to capacity fade [6]. In order to mitigate this problem, attempts have made through coating of metal oxides over LiCoO<sub>2</sub> particles [7-10]. The coating reduces the direct contact with electrolyte and protects the original structure during charging/discharging process. In the present work, newly developed polymeric resin process was used for coating of rare earth oxides (Sm<sub>2</sub>O<sub>3</sub>, La<sub>2</sub>O<sub>3</sub>) over LiCoO<sub>2</sub> nanoparticles. The prepared rare earth oxides (Sm<sub>2</sub>O<sub>3</sub>, La<sub>2</sub>O<sub>3</sub>) coated LiCoO<sub>2</sub> powders were characterized using TG/DSC, FTIR, XRD, SEM and XRF techniques. The electrical conductivities were evaluated through impedance measurements for

pure, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated nanocrystalline LiCoO<sub>2</sub> particles.

## 2. EXPERIMENTAL

LiNO<sub>3</sub>(s.d fine), Co(NO<sub>3</sub>)<sub>2</sub>.6H<sub>2</sub>O (Qualigens), citric acid anhydrous (Qualigens) and ethylene glycol (merck chemicals) were used for the synthesis of nanocrystalline LiCoO<sub>2</sub> particles by Pechini process. Required quantities of metal nitrate, citric acid and ethylene glycol solutions were prepared separately and mixed by keeping total metal ion to citric acid and ethylene glycol ratio as 1 : 1 : 1 under stirring condition. The mixed solution was evaporated at 80°C to remove excess water. After 6-8 hours, it has turned into viscous resin. Further, the resin was heated at 150°C for 12 hours to obtain the polymeric intermediate. The polymeric intermediate was grounded and calcined at 500°C for 12 hours to obtain LiCoO<sub>2</sub> nanoparticles.

For Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coating over LiCoO<sub>2</sub> particles, polyacrylic acid (LR grade, National chemicals), ethylene glycol (merck), samarium nitrate (AR grade, CDH), lanthanum nitrate (SRL chemicals,) and nanocrystalline LiCoO<sub>2</sub> particles were used. The required quantity of LiCoO<sub>2</sub> particles were dispersed in acetone and sonicated for 30 minutes to remove the agglomerations and then acetone was removed by drying in hot air oven. The obtained dried LiCoO<sub>2</sub> particles were dispersed in ethanol through sonication (A). The 10 : 2 molar ratio of polyacrylic acid and ethylene glycol solutions were mixed under constant stirring. The obtained clear solution was evaporated at 80°C to remove excess water. Stoichiometric amounts of samarium nitrate / lanthanum nitrate solution was added to the PAA and EG solution under constant stirring to maintain the molar ratio of total metal ions to PAA and EG as 1 : 10 : 2. Further evaporation, leads to the formation of polymeric resin (B). A and B were mixed under vigorous stirring and the evaporation was continued for 6 hours. Finally, black coloured solid mass was obtained and was calcined at 500°C for 6 hours to obtain Sm<sub>2</sub>O<sub>3</sub> / La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> nanoparticles.

TG/DSC curves of the polymeric resins of Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated nanocrystalline LiCoO<sub>2</sub> samples were recorded at the heating rate of

10<sup>0</sup>C for minute between 30<sup>0</sup>C and 600<sup>0</sup>C using TA instrument SDT Q600 V20.5. FTIR spectra were recorded using shimadzu FTIR-8000 spectrometer. Powder X-ray diffraction patterns were recorded using X'pert PRO MPD, PANalytical (Philips) X-ray powder diffractometer with Cu K $\alpha$  radiation of wavelength 1.54 Å at a scan rate of 2<sup>0</sup> per minute. The microstructures of all the prepared samples were imaged using scanning electron microscope (Hitachi, S-3400N model). The percentage of elements present in the samples were examined using X-ray fluorescence spectrometry (Bruker S4 Pioneer model). The impedance data of all the prepared samples were recorded using Novacontrol Alpha A high performance frequency analyzer.

### 3. RESULTS AND DISCUSSION

#### 3.1. TG / DSC

TG/DSC curves of Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> polymeric resins coated LiCoO<sub>2</sub> nanoparticles are shown in fig.1 a, b. From fig.1a, the observed weight loss about 1.3% in TG curve between 30<sup>0</sup>C and 130<sup>0</sup>C is due to the removal of adsorbed moisture and the weight loss about 2 % between 170<sup>0</sup>C and 435<sup>0</sup>C is due to the decomposition of organic derivatives as well as removal of nitrates. The respective exothermic peaks were observed in DSC curve. TG curve does not show any more weight loss above 500<sup>0</sup>C, which indicates the complete removal of volatiles, nitrates and organic derivatives from the polymeric resin.

Fig.1 TG/DSC curves of a) Sm<sub>2</sub>O<sub>3</sub> and b) La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> polymeric resins.

From fig.1 b, the weight loss about 1.2 % between 30<sup>0</sup>C and 130<sup>0</sup>C is due to the removal of

adsorbed moisture and the respective endothermic peak was observed in DSC curve. The weight loss about 2.3 % between 150<sup>0</sup>C and 465<sup>0</sup>C with two exothermic peaks in DSC curve indicates the decomposition of organic derivatives as well as removal of nitrates.

#### 3.2 FTIR

FTIR spectra of bare, resin, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> nanoparticles are shown in fig.2 a, b. From fig.2 a, b, bare LiCoO<sub>2</sub> exhibited three peaks at 510 cm<sup>-1</sup>, 550-560 cm<sup>-1</sup> and 580-610 cm<sup>-1</sup> and correspond to the asymmetric stretching modes of [CoO<sub>6</sub>] octahedra in LiCoO<sub>2</sub> [11]. For resin coated LiCoO<sub>2</sub>, the observed IR peaks at 1577 cm<sup>-1</sup> and 1475 cm<sup>-1</sup> correspond to the asymmetric stretching modes of COO<sup>-</sup> groups. The sharp IR peak at 1384 cm<sup>-1</sup> corresponds to NO<sub>3</sub><sup>-</sup> ions [12-13]. The band between 1020-1220 cm<sup>-1</sup> is due to the stretching vibration of C-O-C groups [14].

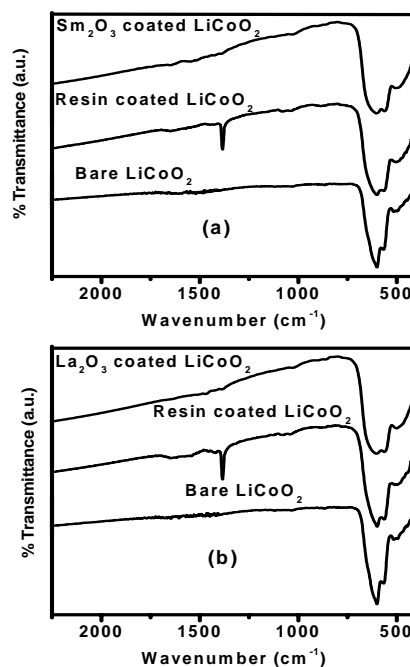

Fig.2 FTIR spectra of a) bare and resin, Sm<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> and b) bare and resin, La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> particles.

For Sm<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub>, the observed IR peaks at 530 cm<sup>-1</sup> and 610 cm<sup>-1</sup> attributed to the stretching modes of Sm<sub>2</sub>O<sub>3</sub> structure and the shifting and broadening of the peaks at 550-560 cm<sup>-1</sup> and 580-610 cm<sup>-1</sup> are due to the formation of Sm<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> structure. For La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub>, the observed peaks at 450 cm<sup>-1</sup> and 640 cm<sup>-1</sup> assigned to the stretching mode of La-O from La<sub>2</sub>O<sub>3</sub> structure [15]. The shifting and broadening of the band at 580-610 cm<sup>-1</sup> may be due to the formation of La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> structure.

### 3.3 XRD

The XRD patterns of bare, resin,  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  nanoparticles are shown in fig.4a,b. From fig.3 a,b, the XRD patterns of the polymeric resin,  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles did not exhibit any extra new peaks corresponding to  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  phases, which indicates that the coating may be in an amorphous phase. Also, XRD patterns of bare,  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  nanoparticles indicate that coating of oxides did not effect the crystalline phase of the  $\text{LiCoO}_2$  nanoparticles, which is confirmed by comparing the observed XRD peaks with standard JCPDS data.

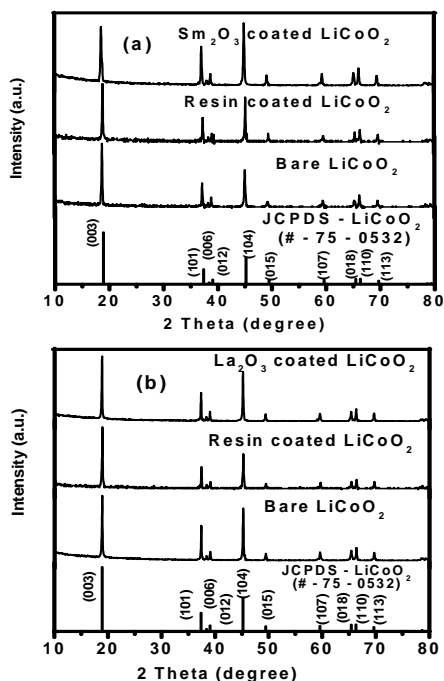

Fig.3 XRD patterns of a) bare,  $\text{Sm}_2\text{O}_3$  polymeric resin and  $\text{Sm}_2\text{O}_3$  coated  $\text{LiCoO}_2$  and b) bare,  $\text{La}_2\text{O}_3$  polymeric resin and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles.

### 3.4 SEM

SEM micrographs of  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated

Fig.4 SEM micrographs of  $\text{Sm}_2\text{O}_3$  coated  $\text{LiCoO}_2$  (a,b) and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles (c,d).

$\text{LiCoO}_2$  nanoparticles at different magnifications are shown in fig.4a-d. Fig.4 a-b, show the SEM images of the  $\text{Sm}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles. Fig.4 c-d, show the SEM images of  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles. All images show a very thin nano size layer over the agglomerated  $\text{LiCoO}_2$  nanoparticles, which may be due to  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coating over the agglomerated  $\text{LiCoO}_2$  nanoparticles.

Further, presence of  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  in  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  nanoparticles are confirmed from the elemental analysis of the measured XRF spectra.

### 3.5. XRF

XRF spectra of  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  nanoparticles are shown in fig. 5a,b. From fig.5a,b, the presence of  $\text{Sm}_2\text{O}_3$ ,  $\text{La}_2\text{O}_3$  and  $\text{CoO}$  in  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles are confirmed from the observed characteristic peaks.

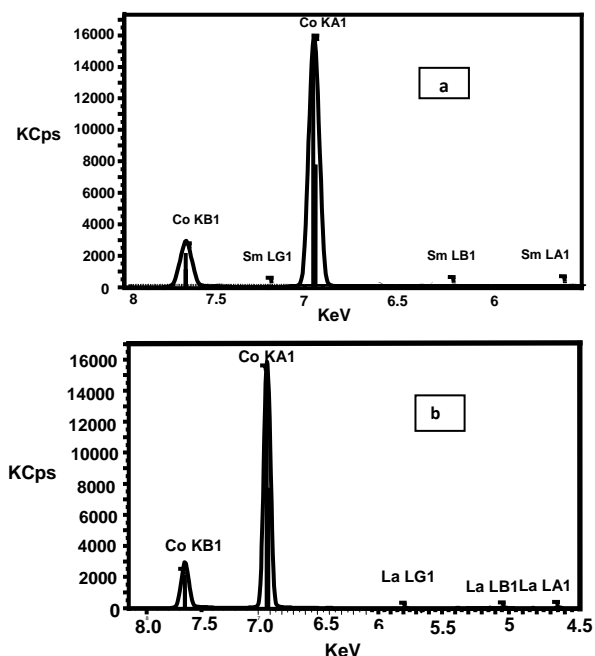

Fig.5 XRF spectra of a)  $\text{Sm}_2\text{O}_3$  coated  $\text{LiCoO}_2$  and b)  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  particles.

Lithium is not detected, since it is a light element. So, excluding the percentages of  $\text{Sm}_2\text{O}_3$ ,  $\text{La}_2\text{O}_3$  and  $\text{CoO}$ , the remaining percentage corresponds to the presence of  $\text{Li}_2\text{O}$ . The  $\text{Sm}_2\text{O}_3$ ,  $\text{La}_2\text{O}_3$  and  $\text{CoO}$  percentages are given in the table 1. Hence, XRF results confirm the presence of  $\text{Sm}_2\text{O}_3$ ,  $\text{La}_2\text{O}_3$  and  $\text{CoO}$  in  $\text{Sm}_2\text{O}_3$  and  $\text{La}_2\text{O}_3$  coated  $\text{LiCoO}_2$  nanoparticles.

Material	CoO	Sm <sub>2</sub> O <sub>3</sub>	La <sub>2</sub> O <sub>3</sub>
Sm <sub>2</sub> O <sub>3</sub> coated LiCoO <sub>2</sub>	83.930	1.849	
La <sub>2</sub> O <sub>3</sub> coated LiCoO <sub>2</sub>	84.980		1.810

Table 2. Percentages of CoO, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> exist in Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> nanoparticles.

### 3.6. Electrical Conductivity Studies

Fig.6 shows the impedance plots of bare, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> nanoparticles. From fig.6, the observed two overlapped semicircles were analyzed using win fit software. The first and second semi circles indicate the grain interior and grain boundary effects respectively [16]. The grain interior ( $R_{gi}$ ) and the grain boundary ( $R_{gb}$ ) resistances of bare, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> sample pellets sintered at 200<sup>o</sup>C for half an hour are obtained respectively from the intercepts of first and second semicircles with the real axis. The evaluated electrical conductivities of bare, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub>

Fig.6 Impedance ( $Z'$  and  $-Z''$ ) plots of bare, Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated nanocrystalline LiCoO<sub>2</sub> particles.

coated LiCoO<sub>2</sub> particles are found to be  $6.597 \times 10^{-6} \text{ ohm}^{-1} \text{ cm}^{-1}$ ,  $4.766 \times 10^{-6} \text{ ohm}^{-1} \text{ cm}^{-1}$  and  $4.336 \times 10^{-6} \text{ ohm}^{-1} \text{ cm}^{-1}$  respectively. It is observed that the conductivities of Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> particles are less compared to bare LiCoO<sub>2</sub>, which may be due to the presence of nanosize Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> layers over the LiCoO<sub>2</sub> particles. The nano size Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> layers protect the LiCoO<sub>2</sub> structure during charge/discharge, which may enhance the capacity retention.

### 4. CONCLUSION

Nanocrystalline LiCoO<sub>2</sub> and Sm<sub>2</sub>O<sub>3</sub>, La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> particles were synthesized using Pechini and

novel polymeric resin processes respectively. Formation of [CoO<sub>6</sub>], Sm<sub>2</sub>O<sub>3</sub> and La-O of La<sub>2</sub>O<sub>3</sub> structures are confirmed from FTIR spectral results. The amorphous nature of the Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> layers over LiCoO<sub>2</sub> particles are confirmed from the observed XRD results. The presence of Sm<sub>2</sub>O<sub>3</sub>, La<sub>2</sub>O<sub>3</sub> and CoO are confirmed from XRF results. The Sm<sub>2</sub>O<sub>3</sub> and La<sub>2</sub>O<sub>3</sub> coated LiCoO<sub>2</sub> particles are found to have less conductivity, compared to bare LiCoO<sub>2</sub> particles.
